

Lecture 19

Outline

- Review of MAC authentication
- Authenticated encryption

HMAC Properties

- $\text{HMAC}(K, M) = H[(K^+ \oplus \text{opad}) || H((K^+ \oplus \text{ipad}) || M)]$
- HMAC is a hash function, so it has the properties of the underlying hash too
 - It is collision resistant
 - Given $\text{HMAC}(K, M)$, an attacker can't learn M – *one way*
 - If the underlying hash is secure, HMAC doesn't reveal M , but it is still deterministic
- You can't verify a tag T if you don't have K
- This means that an attacker can't brute-force the message M without knowing K

MACs: Summary

- Inputs: a secret key and a message
- Output: a tag on the message
- A secure MAC is unforgeable: Even if David can trick Alice into creating MACs for messages that David chooses, David cannot create a valid MAC on a message that she hasn't seen before
 - Example: $\text{HMAC}(K, M) = H((K^+ \oplus \text{opad}) || H((K^+ \oplus \text{ipad}) || M))$
- MACs do not provide confidentiality

Do MACs provide integrity?

- Do MACs provide integrity?
 - Yes. An attacker cannot tamper with the message without being detected
- Do MACs provide authenticity?
 - It depends on your threat model
 - If only two people have the secret key, MACs provide authenticity: it has a valid MAC, and it's not from me, so it must be from the other person
 - More than one secret key, If a message has a valid MAC, you can be sure it came from *someone with the secret key*, but you can't narrow it down to one person
- Do MACs provide confidentiality?

Authenticated Encryption

Authenticated Encryption: Definition

- **Authenticated encryption (AE):** A scheme that simultaneously guarantees confidentiality and integrity (and authenticity, depending on your threat model) on a message
- Two ways of achieving authenticated encryption:
 - Combine schemes that provide confidentiality with schemes that provide integrity
 - Use a scheme that is designed to provide confidentiality and integrity

Scratchpad: Let's design it together

- You can use:
 - An encryption scheme (e.g. AES-CBC): $\text{Enc}(K, M)$ and $\text{Dec}(K, M)$
 - An unforgeable MAC scheme (e.g. HMAC): $\text{MAC}(K, M)$
- First attempt: Alice sends $\text{Enc}(K_1, M)$ and $\text{MAC}(K_2, M)$
 - Integrity? Yes, attacker can't tamper with the MAC
 - Confidentiality? No, the MAC is not secure
- Idea 1: Let's compute the MAC on the *ciphertext* instead of the plaintext:
 $\text{Enc}(K_1, M)$ and $\text{MAC}(K_2, \text{Enc}(K_1, M))$
 - Integrity? Yes, attacker can't tamper with the MAC
 - Confidentiality? Yes, the MAC might leak info about the ciphertext, but that's okay
- Idea 2: Let's encrypt the MAC too: $\text{Enc}(K_1, M || \text{MAC}(K_2, M))$
 - Integrity? Yes, attacker can't tamper with the MAC
 - Confidentiality? Yes, everything is encrypted

MAC-then-Encrypt or Encrypt-then-MAC?

- Method 1: Encrypt-then-MAC
 - First compute $\text{Enc}(K_1, M)$
 - Then MAC the ciphertext: $\text{MAC}(K_2, \text{Enc}(K_1, M))$
- Method 2: MAC-then-encrypt
 - First compute $\text{MAC}(K_2, M)$
 - Then encrypt the message and the MAC together: $\text{Enc}(k_1, M \parallel \text{MAC}(K_2, M))$
- Which is better?
 - In theory, both are secure if applied properly
 - MAC-then-encrypt has a flaw: You don't know if tampering has occurred until after decrypting
 - Attacker can supply arbitrary tampered input, and you always have to decrypt it
 - Passing attacker-chosen input through the decryption function can cause side-channel leaks
- **Always use encrypt-then-MAC** because it's more robust to mistakes

TLS 1.0 “Lucky 13” Attack

- TLS: A protocol for sending encrypted and authenticated messages over the Internet
- TLS 1.0 uses MAC-then-encrypt: $\text{Enc}(k_1, M \parallel \text{MAC}(k_2, M))$
 - The encryption algorithm is AES-CBC
- The Lucky 13 attack abuses MAC-then-encrypt to read encrypted messages
 - Guess a byte of plaintext and change the ciphertext accordingly
 - The MAC will error, but the time it takes to error is different depending on if the guess is correct
 - Attacker measures how long it takes to error in order to learn information about plaintext
 - TLS will send the message again if the MAC errors, so the attacker can guess repeatedly
- Takeaways
 - Side channel attack: The algorithm is proved secure, but poor implementation made it vulnerable
 - Always encrypt-then-MAC
